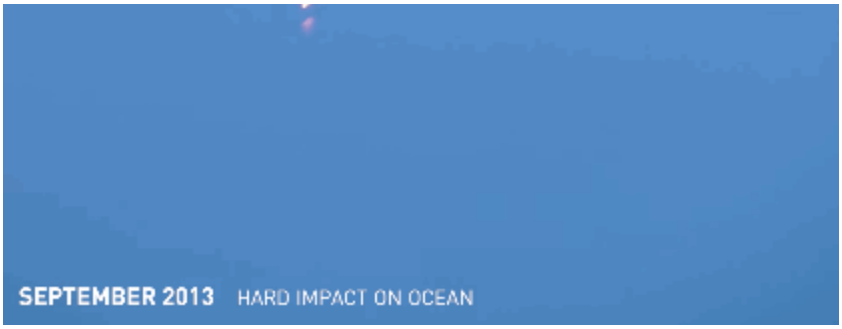
Space X Falcon 9 First Stage Landing Prediction

Assignment: Machine Learning Prediction

Estimated time needed: **60** minutes

Space X advertises Falcon 9 rocket launches on its website with a cost of 62 million dollars; other providers cost upward of 165 million dollars each, much of the savings is because Space X can reuse the first stage. Therefore if we can determine if the first stage will land, we can determine the cost of a launch. This information can be used if an alternate company wants to bid against space X for a rocket launch. In this lab, you will create a machine learning pipeline to predict if the first stage will land given the data from the preceding labs.

Several examples of an unsuccessful landing are shown here:



Most unsuccessful landings are planed. Space X; performs a controlled landing in the oceans.

Objectives

Perform exploratory Data Analysis and determine Training Labels

- create a column for the class
- Standardize the data
- Split into training data and test data

-Find best Hyperparameter for SVM, Classification Trees and Logistic Regression

- Find the method performs best using test data

Import Libraries and Define Auxiliary Functions

```
import piplite
await piplite.install(['numpy'])
await piplite.install(['pandas'])
await piplite.install(['seaborn'])
```

We will import the following libraries for the lab

```
# Pandas is a software library written for the Python programming language for data mani
import pandas as pd
# NumPy is a library for the Python programming language, adding support for large, mult
import numpy as np
# Matplotlib is a plotting library for python and pyplot gives us a MatLab like plotting
import matplotlib.pyplot as plt
#Seaborn is a Python data visualization library based on matplotlib. It provides a high-
import seaborn as sns
# Preprocessing allows us to standarsize our data
from sklearn import preprocessing
```

```
from sklearn import preprocessing
# Allows us to split our data into training and testing data
from sklearn.model_selection import train_test_split
# Allows us to test parameters of classification algorithms and find the best one
from sklearn.model_selection import GridSearchCV
# Logistic Regression classification algorithm
from sklearn.linear_model import LogisticRegression
# Support Vector Machine classification algorithm
from sklearn.svm import SVC
# Decision Tree classification algorithm
from sklearn.tree import DecisionTreeClassifier
# K Nearest Neighbors classification algorithm
from sklearn.neighbors import KNeighborsClassifier
```

This function is to plot the confusion matrix.

```
def plot_confusion_matrix(y,y_predict):
    "this function plots the confusion matrix"
    from sklearn.metrics import confusion_matrix

    cm = confusion_matrix(y, y_predict)
    ax= plt.subplot()
    sns.heatmap(cm, annot=True, ax = ax); #annot=True to annotate cells
    ax.set_xlabel('Predicted labels')
    ax.set_ylabel('True labels')
    ax.set_title('Confusion Matrix');
    ax.xaxis.set_ticklabels(['did not land', 'land']); ax.yaxis.set_ticklabels(['did n
    plt.show()
```

Load the dataframe

Load the data

```
from js import fetch
import io

URL1 = "https://cf-courses-data.s3.us.cloud-object-storage.appdomain.cloud/IBM-DS0321E
resp1 = await fetch(URL1)
text1 = io.BytesIO((await resp1.arrayBuffer()).to_py())
data = pd.read_csv(text1)
```

```
data.head()
```

	FlightNumber	Date	BoosterVersion	PayloadMass	Orbit	LaunchSite	Outcome

90 rows × 83 columns

TASK 1

Create a NumPy array from the column `Class` in `data`, by applying the method `to_numpy()` then

assign it to the variable `Y`,make sure the output is a Pandas series (only one bracket df['name of column']).

```
1 import pandas as pd
2
3 Y = data['Class'].to_numpy()
```

TASK 2

Standardize the data in `X` then reassign it to the variable `X` using the transform provided below.

```
1 # students get this
2 transform = preprocessing.StandardScaler()
3 X = preprocessing.StandardScaler().fit(X).transform(X.astype(float))
```

We split the data into training and testing data using the function `train_test_split`. The training data is divided into validation data, a second set used for training data; then the models are trained and hyperparameters are selected using the function `GridSearchCV`.

TASK 3

Use the function train_test_split to split the data X and Y into training and test data. Set the parameter test_size to 0.2 and random_state to 2. The training data and test data should be assigned to the following labels.

```
X_train, X_test, Y_train, Y_test
```

```
1 X_train, X_test, Y_train, Y_test = train_test_split(X, Y, test_size=0.2, random_state=
2
```

we can see we only have 18 test samples.

```
1 Y_test.shape
```

```
(18,)
```

TASK 4

Create a logistic regression object then create a GridSearchCV object `logreg_cv` with cv = 10. Fit the object to find the best parameters from the dictionary `parameters`.

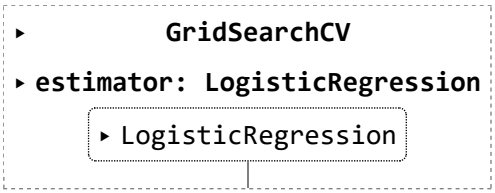
```
parameters ={'C':[0.01,0.1,1],
             'penalty':['l2'],
             'solver':['lbfgs']}
```

```
parameters ={"C":[0.01,0.1,1],'penalty':['l2'], 'solver':['lbfgs']}# l1 lasso l2 ridge
lr=LogisticRegression()

# Create a GridSearchCV object with cv = 10
logreg_cv = GridSearchCV(lr, parameters, cv=10)

# Fit the GridSearchCV object to the training data
logreg_cv.fit(X_train, Y_train)

```



We output the `GridSearchCV` object for logistic regression. We display the best parameters using the data attribute `best_params_` and the accuracy on the validation data using the data attribute `best_score_`.

```
print("tuned hpyerparameters :(best parameters) ",logreg_cv.best_params_)
print("accuracy :",logreg_cv.best_score_)
```

```
tuned hpyerparameters :(best parameters)  {'C': 0.01, 'penalty': 'l2', 'solver': 'lbf
accuracy : 0.8464285714285713
```

TASK 5

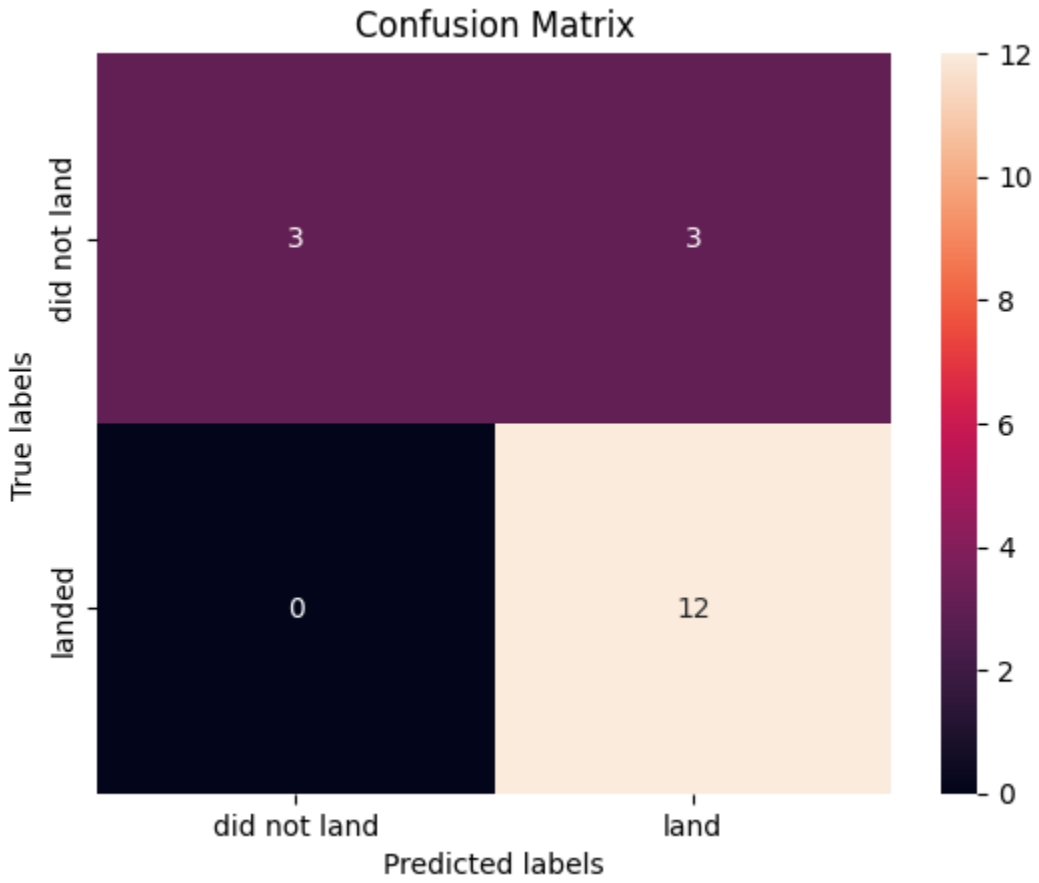
Calculate the accuracy on the test data using the method `score`:

```
test_accuracy = logreg_cv.score(X_test, Y_test)

```

Lets look at the confusion matrix:

```
1 yhat=logreg_cv.predict(X_test)
2 plot_confusion_matrix(Y_test,yhat)
```



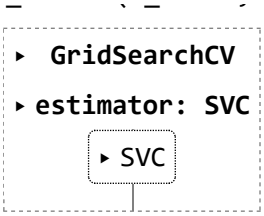
Examining the confusion matrix, we see that logistic regression can distinguish between the different classes. We see that the major problem is false positives.

TASK 6

Create a support vector machine object then create a `GridSearchCV` object `svm_cv` with cv = 10. Fit the object to find the best parameters from the dictionary `parameters`.

```
1 parameters = {'kernel':('linear', 'rbf','poly','rbf', 'sigmoid'),
2               'C': np.logspace(-3, 3, 5),
3               'gamma':np.logspace(-3, 3, 5)}
4 svm = SVC()
```

```
1 # Create a GridSearchCV object with cv = 10
2 svm_cv = GridSearchCV(svm, parameters, cv=10)
3
4 # Fit the GridSearchCV object to the training data
5 svm_cv.fit(X_train, Y_train)
```



```
1 print("tuned hpyerparameters :(best parameters) ",svm_cv.best_params_)
2 print("accuracy :",svm_cv.best_score_)
```

```
tuned hpyerparameters :(best parameters)  {'C': 1.0, 'gamma': 0.03162277660168379, 'k
accuracy : 0.8482142857142856
```

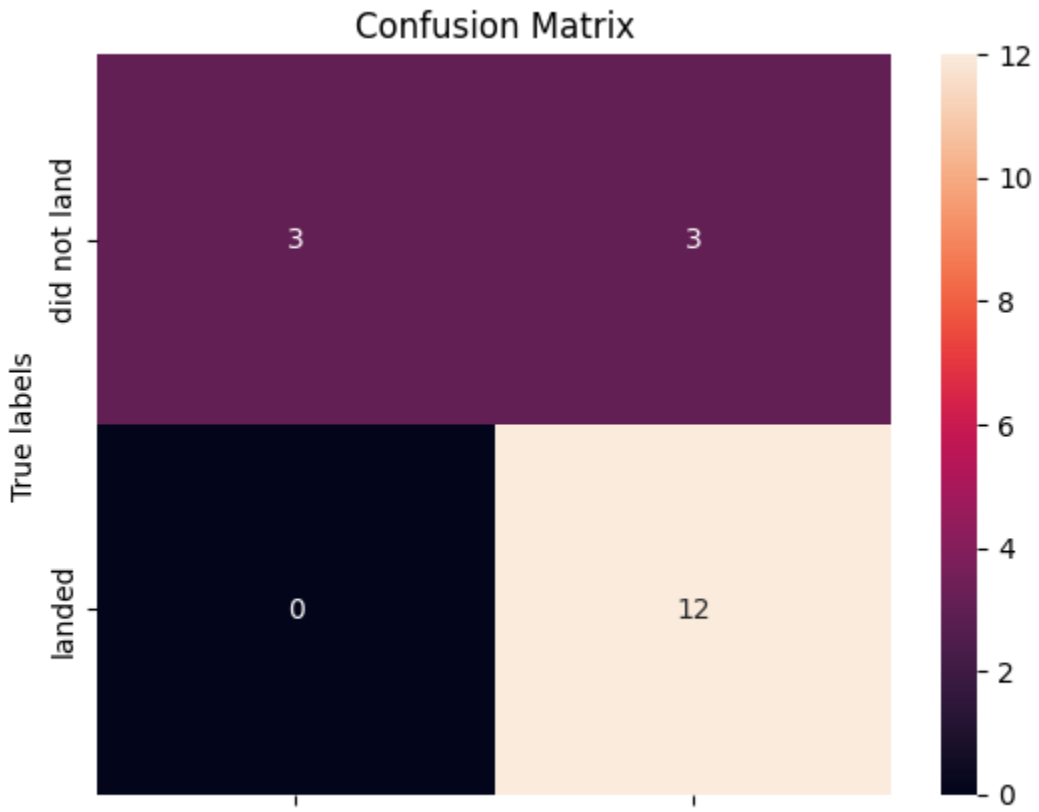
TASK 7

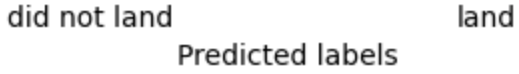
Calculate the accuracy on the test data using the method `score`:

```
1 test_accuracy = svm_cv.score(X_test, Y_test)
2
```

We can plot the confusion matrix

```
1 yhat=svm_cv.predict(X_test)
2 plot_confusion_matrix(Y_test,yhat)
```





TASK 8

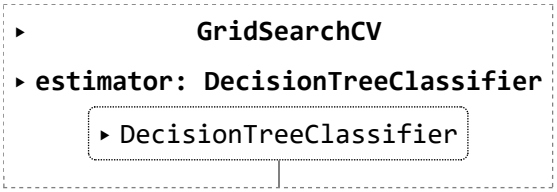
Create a decision tree classifier object then create a `GridSearchCV` object `tree_cv` with cv = 10. Fit the object to find the best parameters from the dictionary `parameters`.

```
parameters = {
    'criterion': ['gini', 'entropy'],
     'splitter': ['best', 'random'],
     'max_depth': [2*n for n in range(1,10)],
     'max_features': ['auto', 'sqrt'],
     'min_samples_leaf': [1, 2, 4],
     'min_samples_split': [2, 5, 10]
}

tree = DecisionTreeClassifier()
```

```
# Create a GridSearchCV object with cv = 10
tree_cv = GridSearchCV(tree, parameters, cv=10)

# Fit the GridSearchCV object to the training data
tree_cv.fit(X_train, Y_train)
```



```
print("tuned hpyerparameters :(best parameters) ",tree_cv.best_params_)
print("accuracy :",tree_cv.best_score_)
```

```
tuned hpyerparameters :(best parameters)  {'criterion': 'gini', 'max_depth': 6, 'max_
accuracy : 0.8767857142857143
```

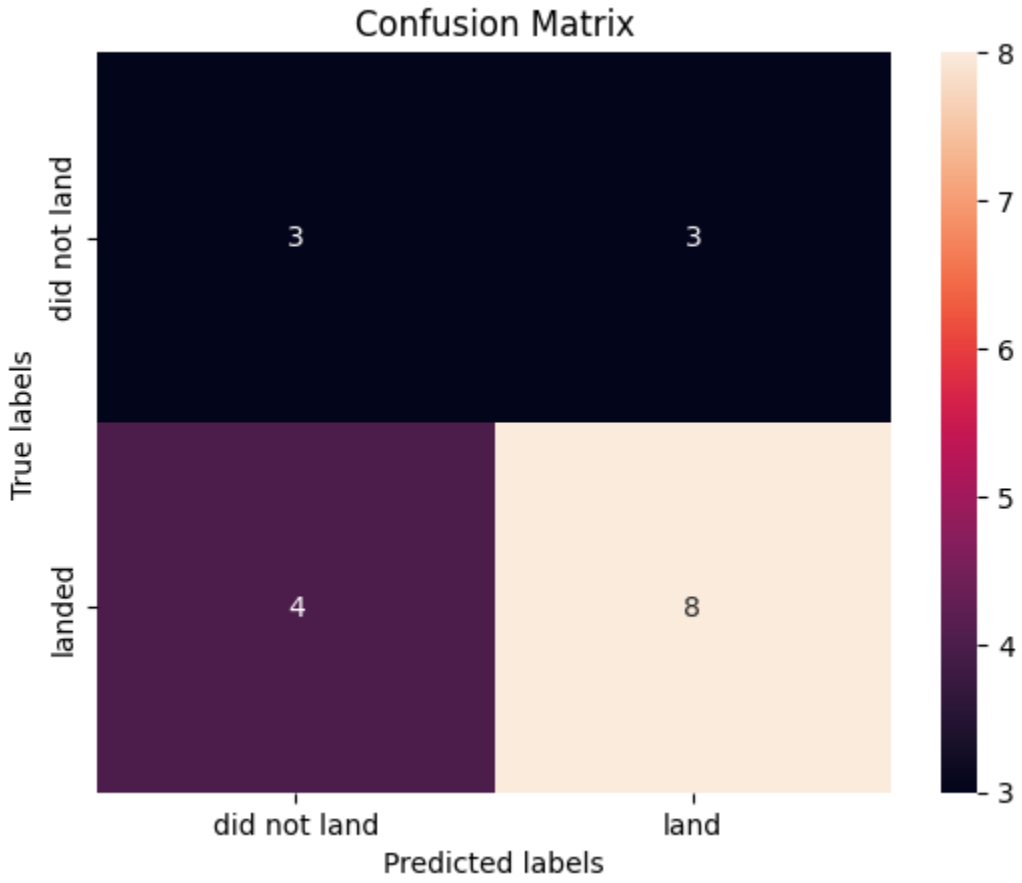
TASK 9

Calculate the accuracy of tree_cv on the test data using the method `score`:

```
test_accuracy = tree_cv.score(X_test, Y_test)
```

We can plot the confusion matrix

```
1 yhat = tree_cv.predict(X_test)
2 plot_confusion_matrix(Y_test,yhat)
```



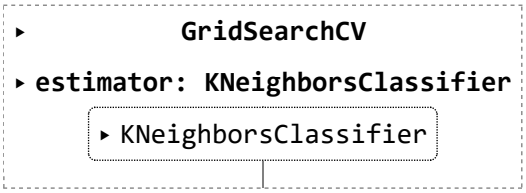
TASK 10

Create a k nearest neighbors object then create a `GridSearchCV` object `knn_cv` with cv = 10. Fit the object to find the best parameters from the dictionary `parameters`.

```
1 parameters = {'n_neighbors': [1, 2, 3, 4, 5, 6, 7, 8, 9, 10],
2               'algorithm': ['auto', 'ball_tree', 'kd_tree', 'brute'],
3               'p': [1,2]}
4
5 KNN = KNeighborsClassifier()
```

```
1 # Create a GridSearchCV object with cv = 10
2 KNN_cv = GridSearchCV(KNN, parameters, cv=10)
3
4 # Fit the GridSearchCV object to the training data
```

```
5 KNN_cv.fit(X_train, Y_train)
6
```



```
1 print("tuned hpyerparameters :(best parameters) ",KNN_cv.best_params_)
2 print("accuracy :",KNN_cv.best_score_)
```

```
tuned hpyerparameters :(best parameters)  {'algorithm': 'auto', 'n_neighbors': 10, 'p
accuracy : 0.8482142857142858
```

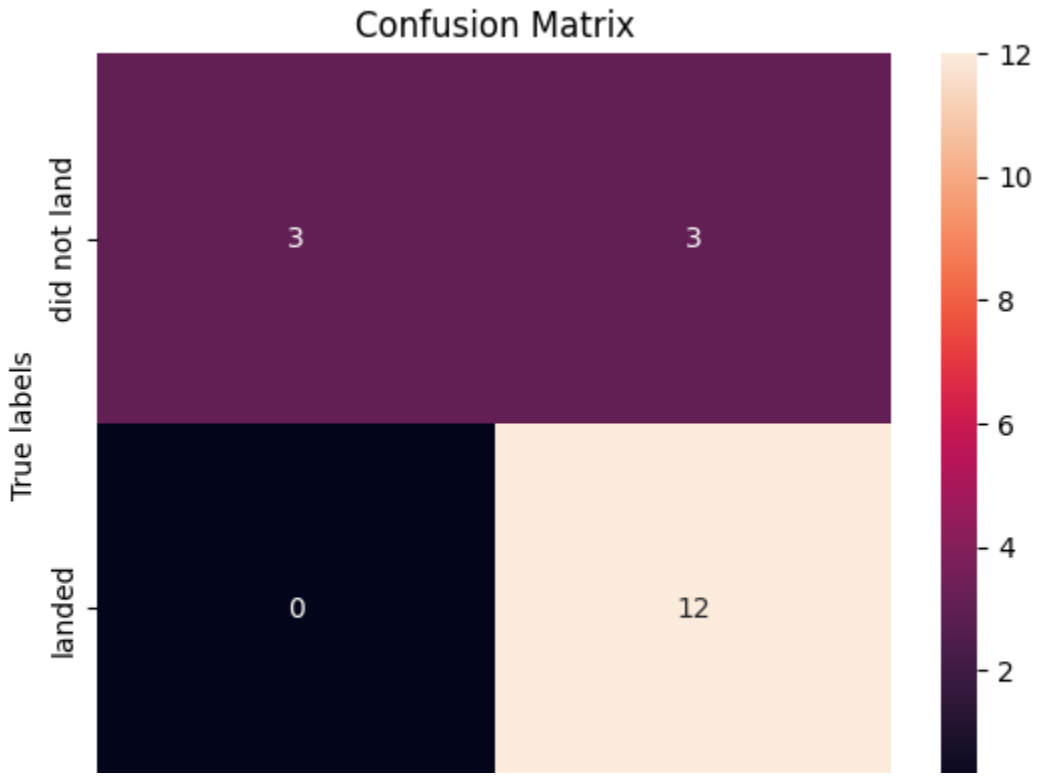
TASK 11

Calculate the accuracy of knn_cv on the test data using the method `score`:

```
1 test_accuracy = KNN_cv.score(X_test, Y_test)
```

We can plot the confusion matrix

```
1 yhat = KNN_cv.predict(X_test)
2 plot_confusion_matrix(Y_test,yhat)
```



TASK 12

Find the method performs best:

```
# Compare test accuracies
model_accuracies = {
    'Logistic Regression': test_accuracy,
    'Support Vector Machine':test_accuracy,
    'Decision Tree': tree_test_accuracy,
    'k-Nearest Neighbors': knn_test_accuracy
}

best_model = max(model_accuracies, key=model_accuracies.get)
print("Best Model:", best_model)
print("Best Model Test Accuracy:", model_accuracies[best_model])
```

```
